

INVESTOR IN PEOPLE

The Patent Office  
Concept House  
Cardiff Road  
Newport  
South Wales  
NP10 8QQ

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

## Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

## Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 08459 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Carbon Dioxide Recirculation

DO NOT REPRODUCE

This invention relates to carbon dioxide recirculating  
5 apparatus. More particularly, the invention relates to  
carbon dioxide recirculating apparatus for heat engines,  
for example gas turbine engines, or fuel cells.

It is known to inject a water based fog into the  
compressor region of a gas turbine engine to increase the  
10 power of the engine. The water is atomised when it is  
sprayed into the compressor region and forms a fog. The  
water droplets forming the fog vaporise and extract latent  
heat of evaporation from the gases in the compressor,  
thereby cooling these gases. This has a beneficial affect  
15 on the power output of the engine. A disadvantage of such  
a system is that evaporation of the water droplets is not  
readily achieved and requires onerous nozzle and spray  
pressure specifications to achieve the required cooling  
effect.

20 According to one aspect of this invention, there is  
provided carbon dioxide recirculating apparatus for an  
arrangement comprising combustion means and a path for a  
flow of gas through the combustion means, the apparatus  
comprising extraction means for extracting gaseous carbon  
25 dioxide from a region of the path downstream of the  
combustion means, condensing means for condensing the  
extracted carbon dioxide, and feed means for feeding the  
condensed carbon dioxide to a region of the path upstream  
of the combustion means.

30 The arrangement preferably comprises a heat engine or  
a fuel cell.

The preferred embodiment of the invention is  
particularly suitable for use in an arrangement in the form  
of a gas turbine engine. In this embodiment, the feed  
35 means may feed the condensed carbon dioxide to a compressor  
region of the gas turbine engine. The extraction means may

be arrangeable downstream of a turbine arrangement of the gas turbine engine.

According to another aspect of this invention there is provided an arrangement comprising combustion means a path  
5 for the flow of gas through the combustion means and carbon dioxide recirculating apparatus comprising extraction means for extracting gaseous carbon dioxide from a first region of the path downstream of the combustion means, condensing means for condensing the extracted carbon dioxide, and feed  
10 means for feeding the condensed carbon dioxide to a second region of the path upstream of the combustion means.

The arrangement may comprise a heat engine or a fuel cell assembly. The heat engine may be a gas turbine having a compressor region in the path of the gas upstream of the  
15 combustion means, and a turbine region in the path of the gas downstream of the combustion means. The compressor means may be a compressor unit.

The condensing means may comprise heat removal means to remove heat from the extracted carbon dioxide. The  
20 condensing means may include compressor means to compress the extracted carbon dioxide. Preferably, the compressor means is arranged between the extraction means and the heat removal means. In the preferred embodiment, the heat removal means comprises cooling means to cool the carbon  
25 dioxide.

The feed means may comprise spray means to spray the condensed carbon dioxide into the second region. Where the arrangement comprises a gas turbine engine, the spray means may spray the condensed carbon dioxide into the compressor  
30 region of the gas turbine engine, preferably to form a fog of the carbon dioxide. The spray means may comprise atomising means, which may be in the form of a nozzle. Preferably, the atomising means comprises a plurality of atomising nozzles, which may be in the form of an array of  
35 nozzles.

The extraction means may comprise a recirculating

amine based extraction means, and may include cooling and heating units to support the operation of the amine based extraction means.

Preferably, the extraction means is arrangeable to  
5 extract carbon dioxide from the exhaust gases downstream of the turbine region.

The compressor region of the engine may comprise first and second compressors, and the feed means may be arrangeable to feed condensed carbon dioxide to the  
10 compressor region between the first and second compressors. Alternatively, or in addition, the feed means may feed the condensed carbon dioxide to the compressor region at an outlet of the compressor region. Alternatively, or in addition, the feed means may be arrangeable to feed the  
15 carbon dioxide at an inlet to the compressor region.

In one embodiment, the feed means may be arrangeable to feed the condensed carbon dioxide to the outlet of the compressor region, whereby the carbon dioxide thereafter passes into a heat exchanger to exchange heat with gases  
20 exiting from the turbine region of the gas turbine engine. Preferably, the heat exchanger comprises a recuperator.

The fuel cell assembly may be arranged to receive carbon dioxide from the carbon dioxide recirculating apparatus. The fuel cell assembly may comprise an anode  
25 and a cathode. Preferably exhaust from the anode is passed to the carbon dioxide recirculating apparatus.

The fuel cell assembly may comprise a compressor for compressing air and other gases to be supplied to the cathode. The fuel cell assembly may comprise a conduit for  
30 directing recirculated carbon dioxide to the anode. Alternatively, or in addition, the fuel cell assembly may comprise a conduit for directing carbon dioxide to the compressor for mixing with air compressed by the compressor. The compressor may be a compressor of the  
35 compressor region of the gas turbine engine.

According to another aspect of this invention, there

is provided a method of recirculating carbon dioxide from a flow of gas through an arrangement comprising combustion means and a path for the flow of gas through the combustion means, the method comprising extracting carbon dioxide from  
5 a first region downstream of the combustion means, condensing the extracted carbon dioxide and thereafter feeding the condensed carbon dioxide to a second region upstream of the combustion means.

Preferably the step of condensing the extracted carbon  
10 dioxide comprises providing heat removal means to remove heat from the carbon dioxide and may also include compressing the carbon dioxide prior to removing said heat from the carbon dioxide.

The heat removal means may comprise cooling means to  
15 cool the carbon dioxide to effect said condensation thereof.

The step of feeding the condensed carbon dioxide to the second region of the engine may comprise spraying the condensed carbon dioxide to the second region. The  
20 spraying of the condensed carbon dioxide may form a fog of the carbon dioxide in the upstream region of the engine.

Preferably the step of feeding the carbon dioxide to the second region of the engine comprises atomising the condensed carbon dioxide.

25 In the preferred embodiment, the engine is a gas turbine engine comprising a compressor region upstream of the combustion means and a turbine region downstream of the combustion means, and the step of extracting carbon dioxide comprises extracting carbon dioxide downstream of the  
30 turbine region of the engine.

In the preferred embodiment, the step of feeding the carbon dioxide to the second region of the path comprises feeding the carbon dioxide to the compressor region of the engine. The compressor region may comprise first and  
35 second compressors arranged in axial flow series in the path and the step of feeding the carbon dioxide to the

compressor region may comprise feeding the carbon dioxide between the first and second compressors and/or to an outlet of the compressor region and/or to an inlet of the compressor region.

5       The engine may comprise heat exchange means to exchange heat between gas entering the combustion means and gas exhausted from the combustion means, preferably downstream of the turbine region. The step of feeding the condensed carbon dioxide to the second region may comprise  
10       feeding the carbon dioxide to gas entering the heat exchange means upstream of the combustion means preferably at the outlet of the compressor region. The heat exchange means may comprise a recuperator.

Embodiments of the invention will now be described by  
15       way of example only with reference to the accompanying drawings in which:-

Fig. 1 shows a sectional view of the upper half of a gas turbine engine;

Fig. 2 is a diagrammatic representation of carbon  
20       dioxide recirculating apparatus;

Fig. 3 is a further diagrammatic representation showing another embodiment of carbon dioxide recirculating apparatus;

Fig. 4 is diagrammatic representation of a further  
25       embodiment of carbon dioxide recirculating apparatus incorporating fuel cell; and

Fig. 5 is a diagrammatic representation of another embodiment of carbon dioxide recirculating apparatus incorporating a fuel cell.

30       With reference to Fig. 1, a ducted fan gas turbine engine generally indicated at 10 has a principal axis X-X. The engine 10 comprises, in axial flow series, an air intake 11, a propulsive fan 12, a compressor region 113 comprising an intermediate pressure compressor 13, and a  
35       high pressure compressor 14, combustion means 115 comprising a combustor 15, and a turbine region 116

comprising a high pressure turbine 16, an intermediate pressure turbine 17, and a low pressure turbine 18. An exhaust nozzle 19 is provided at the tail of the engine 10.

The gas turbine engine 10 works in the conventional  
5 manner so that air entering the intake 11 is accelerated by the fan to produce two air flows: a first air flow into the intermediate pressure compressor 13 and a second air flow which provides propulsive thrust. The intermediate pressure compressor 13 compresses the air flow directed  
10 into it before delivering that air to the high pressure compressor 14 where further compression takes place.

The compressed air exhausted from the high pressure compressor 14 is directed into the combustor 15 where it is mixed with fuel and the mixture combusted. The resultant  
15 hot combustion products then expand through, and thereby drive, the high, intermediate and low pressure turbine 16, 17 and 18 before being exhausted through the nozzle 19 to provide additional propulsive thrust. The high, intermediate and low pressure turbines 16, 17 and 18  
20 respectively drive the high and intermediate pressure compressors 14 and 13 and the fan 12 by suitable interconnecting shafts.

Referring to Fig. 2, there is shown a schematic representation of carbon dioxide recirculating apparatus 20  
25 for use in a gas turbine engine. Fig. 2 shows the compressor region 113, the combustion region 115, and the turbine region 116, of the engine 10 as described above. Fig. 2 also shows the carbon dioxide recirculating apparatus 20 comprising extraction means 22 arranged  
30 downstream of the turbine region 116 in the main flow of gas to be exhausted from the engine 10. The extraction means 22 may comprise any suitable known carbon dioxide extraction arrangement. An example of such an arrangement is a recirculating amine based unit in which amine solvents  
35 such as diethandamine can be employed to remove the carbon dioxide to remove carbon dioxide from the gas in the main

flow downstream of the turbine region 116. Carbon dioxide extracted from the exhaust gases is passed via a line 24 to compressor means in the form of a carbon dioxide compressor unit 26. The resulting carbon dioxide depleted exhaust is  
5 passed to the exhaust nozzle 19.

The compressor unit 26 compresses the extracted carbon dioxide, which is passed via a line 28 to a cooler 30 which condenses the compressed carbon dioxide, and produces  
10 pressurised liquid carbon dioxide at or near ambient temperature. The pressurised liquid carbon dioxide is then passed via a line 32 to feed means in the form of a feed nozzle arrangement 36. The pressurised liquid carbon dioxide is fed by the nozzle arrangement 36 to the  
15 compressor region 115 of the gas turbine engine 10. Specifically, the liquid carbon dioxide is fed to the main duct designated 34 (shown schematically in Fig. 2) between the intermediate pressure compressor 13 and the high pressure compressor 14.

The feed nozzle arrangement 36 comprises an array of  
20 atomising nozzles to spray the liquid carbon dioxide into the main duct 34 between the intermediate and high pressure compressors 13, 14.

As the liquid carbon dioxide is atomised into the duct 34, it partly flashes to the vapour phase. Carbon dioxide  
25 which does not vaporise partly solidifies. This results in a mixture of solid, liquid and gaseous carbon dioxide. The solid carbon dioxide then sublimates to the vapour phase, and the remaining liquid carbon dioxide then vaporises to the vapour phase. This results in a carbon dioxide fog  
30 forming in the duct 34. The sublimation and vaporisation of the carbon dioxide absorbs latent heat of sublimation and vaporisation from the gases in the duct 34 thereby cooling these gases.

Fig. 3 shows a further embodiment, which has many of  
35 the features of Fig. 2, and these features have been designated with the same reference numeral. In Fig. 3, the

carbon dioxide recirculating apparatus is designated 120 and the feed means is designated 136 and comprises a first feed nozzle arrangement 136A and a second feed nozzle arrangement 136B.

5       The line 32 carrying the pressurised liquid carbon dioxide at ambient temperature splits into a first line 132A leading to the first feed nozzle arrangement 136A and a second line 132B leading to the second feed nozzle arrangement 136B. The first feed nozzle arrangement 136A  
10 atomises the liquid carbon dioxide so that it is sprayed into the duct 34 between the intermediate and high pressure compressors 13, 14. This spraying of the carbon dioxide has the same effects upon it as described above, with reference to the spraying of the carbon dioxide into the  
15 duct 34 in Fig. 2. The second feed nozzle arrangement sprays the liquid carbon dioxide into a duct 38 downstream of the high pressure compressor 14, and upstream of the combustor region 115. Again the carbon dioxide sprayed into the duct 38 undergoes the same phase changes as  
20 described above.

Thus, the pressurised liquid carbon dioxide sprayed into the ducts 34 and 38 via the respective arrays of nozzles 136A and 136B form a carbon dioxide fog in the ducts 34 and 38.

25       A heat exchanger in the form of a recuperator 40 is provided in the embodiment shown in Fig. 3, to exchange heat between gases exiting the compressor region 113 and the gases exiting the turbine region 116. The carbon dioxide fed by the second feed nozzle arrangement 136B into  
30 the main flow of gas in the duct 38 flashes to the vapour phase, solidifies, sublimates and vaporises in the same way as described above with reference to Fig. 2. The carbon dioxide, along with other gases in the duct 38 is passed, as indicated by the arrow 39, to one side of a recuperator  
35 40 to exchange heat with exhaust gases from the turbine region 116 passed to the other side of the recuperator 40

as indicated by the arrow 42. The recuperator 40 is provided to increase the heat in the gases entering the combustor 15, which also has the effect of cooling the gases exiting from the turbine region 116 upstream of the  
5 extraction means 22.

The exhaust gases from the turbine region 116 exit the recuperator 40 and are then passed to the carbon dioxide extraction means 22 via the main duct, as indicated by the arrow 44.

10 Fig. 4 is a diagrammatic representation of carbon dioxide recirculating apparatus 10 incorporating a fuel cell 50. The carbon dioxide recirculating apparatus 20 in Fig. 4 is shown in use in a gas turbine engine 10. The features of the gas turbine engine 10 and the carbon  
15 dioxide recirculating apparatus 20 are given the same reference numerals as in Fig. 2

The fuel cell 50 is, in the embodiment shown, a fuel cell of a type known generally as a solid oxide fuel cell. The fuel cell 50 comprises an anode 52 and a cathode 54.

20 The compressor region 113 of the gas turbine engine 10 supplies compressed air to the cathode 54 via a recuperator 140 along a line 56. In the anode 52, the hydrogen in the fuel reacts with oxygen ions produced at the cathode 54 (as explained below) to produce water molecules and electrons  
25 creating an electric current. This is an exothermic reaction and the heat generated is transferred to the incoming compressed air in the line 56 in the recuperator 140. The output from the cathode 54 is passed along a line 58 (via the recuperator 140) to a combustor 160. If  
30 desired the combustor 160 can be the combustor 15 of the engine 10.

A fuel mixture (labelled FUEL in Fig. 4) is supplied to a supplementary compressor 62 which also received recirculated carbon dioxide from the carbon dioxide  
35 recirculating apparatus 20 (as explained below). The fuel mixture comprises fuel, hydrogen, carbon dioxide, carbon

monoxide and hydrocarbons and is compressed by the supplementary compressor 62 and fed via a line 64 to the anode 52 of the fuel cell.

5 The oxygen in the compressed air in the cathode 54 is electrically charged to provide oxygen ions. The oxygen ions pass through/across the solid oxide electrolyte membrane in the fuel cell 50 between the cathode 54 and the anode 52, to react with the hydrogen in the anode 52 (as described above).

10 The exhaust products from the anode 52 are fed via a line 66 to the carbon dioxide extraction means 22. The carbon dioxide is extracted from the exhaust products and passed via the line 24 to the carbon dioxide compressor unit 26 to be recirculated, via the cooler 30, back to the  
15 supplementary compressor 62.

The remaining exhaust products entering the carbon dioxide extraction means are passed to the combustor 160 along a line 68 and fed back to the turbine arrangement 116 of the engine 10 along a line 70. This powers the turbine  
20 arrangement to the drive the compressor arrangement 113. The exhaust from the turbine arrangement 116 is exhausted to atmosphere via the exhaust nozzle 19, (labelled EXHAUST).

As an alternative, or in addition, as shown in broken  
25 lines, the recirculated carbon dioxide flowing along the line 28 could be fed via a line 128 to the compressor arrangement 113.

Another embodiment of a carbon dioxide recirculating apparatus 20 incorporating a fuel cell 50 is shown in Fig.  
30 5. The carbon dioxide recirculating apparatus 20 is shown in use in a gas turbine engine 10. The features of the gas turbine engine 10 and the carbon dioxide recirculating apparatus are given the same reference numerals as in Fig. 2.

35 The fuel cell 50 shown in Fig. 5 is of a type known as a molten carbonate fuel cell. In such a fuel cell 50 there

is a requirement for carbon dioxide on the air/oxygen side of the fuel cell 50, i.e. the cathode 54.

The compressor region 113 receives recirculated carbon dioxide via line 128A (as explained below), in addition to  
5 air. The compressed air and carbon dioxide is passed via the line 56 to the cathode 54 of the fuel cell 50. Some of the reaction products from the cathode are passed via the line 58 to the combustor 160. In some embodiments, the combustor 160 could be the combustor 15 of the gas turbine  
10 engine 10.

The remainder of the reaction products from the cathode 54 are passed via a line 70 to the turbine arrangement 116, which drives the compressor arrangement 113 as explained above. The exhaust 72 from the turbine  
15 arrangement 113 drives a free power turbine 74, which, in turn, drives a further compressor 76 via a shaft 78.

The exhaust from the free power turbine 74 is passed via a line 90 to a heat exchanger or recuperator 92 where heat is exchanged with compressed gases exiting from the  
20 compressor arrangement 113 prior to entering the cathode 54.

After exiting the recuperator 92, the gases from the free power turbine 74 are exhausted to atmosphere via the exhaust nozzle 19.

25 The combustion products from the combustor 160 are passed via a line 80 to the further compressor 76. The further compressor 76 also receives recirculated carbon dioxide (as explained above) via a line 128B. The compressed combustion products and carbon dioxide are  
30 passed to the cathode 54 via a line 82.

The anode 52 receives fuel via the line 64. The reaction products pass from the anode 52 by a line 66. Some of the reaction products may be recirculated via a line 84 and a supplementary compressor 86 to be passed back  
35 into the anode 52.

The reaction products from the anode 52, which are not

recirculated, are split into two. Some of the reaction products from the anode 52 are passed via a line 66A to the combustor 160 and are mixed with the incoming reaction products from the cathode 54 and combusted. The remainder  
5 of the reaction products from the anode 52 are passed via a line 66B to the carbon dioxide extraction means 22.

The carbon dioxide is extracted and passed via the line 24 to the carbon dioxide compressor unit 26 and then cooled by the cooler 30. The cooled carbon dioxide exits  
10 the cooler 30 via the line 128. Some of the cooled carbon dioxide is passed via the line 128A to the compressor arrangement 113. The remainder of the cooled carbon dioxide is passed via the line 128B to the compressor 76, as described above.

15 The remaining cathode reaction products in the carbon dioxide extraction means 22 are passed via the line 68 to the combustor 160 to be combusted.

The above described embodiments have the advantage that the fog sprayed into the compressor region is formed  
20 from liquid carbon dioxide that flashes under more favourable and more easily achieved conditions than water. As a result, a fog with a small droplet size is generated more readily than with water. This results in there being less demanding nozzle and spray pressure specifications  
25 than are necessary with water.

Further, the above described embodiments have the advantage that the use of carbon dioxide means that complete evaporation of the fog can be more easily achieved than with water, due to the high saturated vapour pressure  
30 of the carbon dioxide at ambient temperatures. This permits the use of carbon dioxide based fog cooling to be used in conditions that would be too confined in length to achieve adequate evaporation with a water based fog. A further benefit is that carbon dioxide recirculation is  
35 achieved with less compression in the recirculating system than with a water based recirculation. It is possible thus

to enhance efficiency and power of the engine more substantially than with the use of water.

The use of carbon dioxide has the further advantage that cooling could be carried out at the inlet of the  
5 compressors of a gas turbine engine, and could also be used in other engines, for example reciprocating engines. Indeed, the invention could be applied to a wide range of cycles using heat engines and/or fuel cells as the primary source of carbon dioxide.

10 Whilst endeavouring in the foregoing specification to draw attention to those features of the invention believed to be of particular importance it should be understood that the Applicant claims protection in respect of any patentable feature or combination of features hereinbefore  
15 referred to and/or shown in the drawings whether or not particular emphasis has been placed thereon.

**Claims:-**

1. Carbon dioxide recirculating apparatus for an arrangement having combustion means and a path for a flow  
5 of gas through the combustion means, the apparatus comprising extraction means for extracting gaseous carbon dioxide from a first region of the path downstream of the combustion means, condensing means for condensing the extracted carbon dioxide, and feed means for feeding the  
10 condensed carbon dioxide to a second region of the path upstream of the combustion means.
2. Carbon dioxide recirculating apparatus according to Claim 1 wherein the condensing means comprises heat removal means, to remove heat from the extracted carbon dioxide,  
15 and compressor means to compress the extracted carbon dioxide, the compressor means being arranged between the extraction means and the heat removal means.
3. Carbon dioxide recirculating apparatus according to Claim 2, wherein the heat removal means comprises cooling  
20 means to cool the compressed carbon dioxide.
4. Carbon dioxide recirculating apparatus according to Claim 1, 2 or 3, wherein the feed means comprises spray means to spray the condensed carbon dioxide into the second region of the path to form a fog of the carbon dioxide.
- 25 5. Carbon dioxide recirculating apparatus according to Claim 4, wherein the spray means comprises atomising means.
6. Carbon dioxide recirculating apparatus according to Claim 5, wherein the atomising means comprises a nozzle.
7. A combustion arrangement comprising combustion means,  
30 a path for a flow of gas through the combustion means and carbon dioxide recirculating apparatus as claimed in any preceding claim.
8. An arrangement according to Claim 7, wherein the arrangement is in the form of a heat engine or a fuel cell.
- 35 9. An arrangement according to Claim 8, wherein the heat engine comprises a gas turbine engine having a compressor

region in the path upstream of the combustion means and a turbine region in the path downstream of the combustion means.

10. An arrangement according to Claim 9, wherein the  
5 extraction means is arrangeable to extract carbon dioxide from the exhaust gases downstream of the turbine region.

11. An arrangement according to Claim 9 or 10, wherein the feed means is arrangeable to feed condensed carbon dioxide to the compressor region.

10 12. An arrangement according to Claim 9, 10 or 11, wherein the compressor region comprises first and second compressors arranged in the path in axial flow series, and the feed means is arranged to feed the condensed carbon dioxide to one or more of: the inlet to the compressor  
15 region; between the first and second compressors; and the outlet of the compressor region.

13. An arrangement according to Claim 9, 10 or 11, wherein the engine includes a heat exchanger to exchange heat between gas entering the combustion means and heat  
20 exhausted from the combustion means, and the feed means is arranged to feed at least some of the condensed carbon dioxide to the outlet of the compressor region upstream of the heat exchanger.

14. An arrangement according to Claim 13, wherein the  
25 compressor region comprises first and second compressors and the feed means is arranged also to feed some of the condensed carbon dioxide between the first and second compressors and/or to the inlet of the compressor region.

15. A combustion arrangement according to any of Claims 7  
30 to 14 including a fuel cell assembly to receive carbon dioxide from the carbon dioxide recirculating apparatus.

16. A combustion arrangement according to Claim 15, wherein the fuel cell assembly comprises a cathode to receive carbon dioxide from the carbon dioxide  
35 recirculating apparatus and an anode, the exhaust from the anode being passed to the carbon dioxide recirculating

apparatus.

17. A combustion arrangement according to Claim 16 comprising a compressor for receiving recirculated carbon dioxide and for compressing gases prior to said gases being  
5 passed to the cathode.
18. A combustion arrangement according to claim 16 or 17, wherein recirculated carbon dioxide is passed to the anode.
19. A combustor arrangement according to Claim 17 or 18 including a turbine driven by gases exhausted from said  
10 cathode, the turbine being arranged to drive the compressor.
20. A combustor arrangement according to Claim 19, wherein the turbine comprises a free power turbine driven by gases exhausted from a principal turbine.
- 15 21. A combustor arrangement according to Claim 20, wherein the principal turbine is driven by gases exhausted from the cathode, and the arrangement further includes a principal compressor driven by the principal turbine, the principal  
20 compressor receiving recirculated carbon dioxide and compressing gases prior to said gases being passed to the cathode.
22. A method of recirculating carbon dioxide from a flow of gas through an arrangement comprising combustion means and a path for the flow of gas through the combustion  
25 means, the method comprising extracting carbon dioxide from a first region downstream of the combustion means, condensing the extracted carbon dioxide and thereafter feeding the condensed carbon dioxide to a second region upstream of the combustion means.
- 30 23. A method according to Claim 22, wherein the step of condensing the extracted carbon dioxide comprises providing heat removal means to remove heat from the carbon dioxide and compressing the carbon dioxide prior to removing said heat from the carbon dioxide.
- 35 24. A method according to Claim 23, wherein the heat removal means comprises cooling means to cool the carbon

dioxide to effect said condensation thereof.

25. A method according to Claim 22, 23 or 24, wherein the step of feeding the condensed carbon dioxide to the second region of the engine comprises spraying the condensed  
5 carbon dioxide to the second region to form a fog of the carbon dioxide in the second region.

26. A method according to any of Claims 22 to 25, wherein the step of feeding the carbon dioxide to the second region of the arrangement comprises atomising the condensed carbon  
10 dioxide.

27. A method according to any of Claims 22 to 26, wherein the arrangement comprises a heat engine or a fuel cell.

28. A method according to Claim 25, wherein the engine is a gas turbine engine comprising a compressor region  
15 upstream of the combustion means, and a turbine region downstream of the combustion means, and the step of extracting carbon dioxide comprises extracting carbon dioxide downstream of the turbine region.

29. A method according to Claim 28, wherein the step of  
20 feeding the carbon dioxide to the second region of the path comprises feeding the carbon dioxide to the compressor region of the engine.

30. A method according to Claim 28 or 29, wherein the compressor region comprises first and second compressors  
25 arranged in axial flow series in the path, and the step of feeding the carbon dioxide to the second region of the path comprises feeding the carbon dioxide to one or more of: the inlet of the compressor region; between the first and second compressors; and to the outlet of the compressor  
30 region.

31. A method according to Claim 28 or 29, wherein the engine may comprise a heat exchanger to exchange heat between gas entering the combustion means and gas exhausted from the combustion means, and the step of feeding the  
35 condensed carbon dioxide to the second region comprises feeding the carbon dioxide to the outlet of the compressor

region.

32. A method according to Claim 31, wherein the compressor region comprises first and second compressors and the step of feeding the condensed carbon dioxide to the compressor  
5 region also includes feeding some of the condensed carbon dioxide between the first and second compressors and/or to the inlet of the compressor region.

33. Carbon dioxide recycling apparatus substantially as herein described with reference to Figs. 2 and 3 of the  
10 drawings.

34. A combustion arrangement substantially as herein described with reference to Figs. 2 and 3 of the drawings.

35. A method of recirculating carbon dioxide substantially as herein described with reference to Figs. 2 and 3 of the  
15 accompanying drawings.

36. Any novel subject matter or combination including novel subject matter disclosed herein, whether or not within the scope of or relating to the same invention as any of the preceding claims.

ABSTRACTCarbon Dioxide Recirculation

5        Carbon dioxide recirculating apparatus (20, 120) is disclosed for use in an arrangement having combination means (115) and a path for the flow of a gas through the combustion means (115). The apparatus (20, 120) comprises extraction means (221) for extracting carbon dioxide from a  
10 first region of the path downstream of the combustion means (115). It further includes condensing means (26, 30) for condensing the extracted carbon dioxide, and feed means (36, 136) for feeding the condensed carbon dioxide to a second region of the path upstream of the combustion means.
